CONVERTING PHASE NOISE TO JITTER
The first step in calculating the equivalent rms jitter is to obtain the integrated phase noise power over the frequency range of interest, i.e., the area of the curve, A. The curve is broken into a number of individual areas (A1, A2, A3, A4), each defined by two data points.

Following equation or formula is used for RF phase noise to jitter converter calculator. The term phase jitter is the equivalent of RF phase noise in the digital domain. Hence it is often required to convert phase noise to jitter for various reasons. Useful converters and calculators

Both phase noise and phase jitter look at the effect of small phase deviations on a signal. Phase noise is the easier concept to grasp as it can be seen on a spectrum analyzer. Phase jitter is less easy to visualise, and often phase jitter, measured in radians RMS is seldom mentioned and yet it is just as valid a method of specifying the phase perturbations on a signal.

As shown in the figure first integrated phase noise is derived from f1 to f5, let this integrated phase noise is A. From this integrated phase noise, rms phase jitter is obtained using following equation. A= 10*log 10 (A1+A2+A3) Phase jitter (radians) φ = (2 x 10 A/10) 1/2

This article first briefly reviews the measurement setups for clock period jitter and phase noise. The relationship between the period jitter and the phase-noise spectrum is then described. Finally, a simple equation to convert the phase-noise spectrum to the period jitter is presented. Period Jitter and Phase Noise: Definition and Measurement

To get RMS Jitter, in radians, from Phase Noise you must integrate the Phase Noise. What are the units of integrated Phase Noise and how do they cancel. The equation I am currently using for this is A = Phase Noise (L (f)) + 10*log 10 (frequency 2 - frequency 1) and to generate the RMS Jitter value in radians I am using sqrt (2*10^ (A/10)).

One way occurs when the noise causes the data waveform to dip below the decision threshold voltage at the sampling instance (voltage noise). Also noise can cause errors by inducing jitter (timing noise).

Equating Phase Noise to Jitter In the absence of 1/f noise in a region where the phase noise displays a -20 dBc/Hz slope, the rms cycle jitter can be related to the phase noise by: 2 2 3 f f f c osc σ = (9) 3 2 2 osc c f Ef σ = (10) Example: A 141 MHz oscillator has a phase noise of -56.75 dBc/Hz at a 1 kHz offset frequency. This corresponds to a cycle-to-cycle jitter of 0.866 ps ...

Phase Noise and Jitter - Keysight
Jitter vs. Phase Noise Jitter is usually a time domain term, while phase noise is a frequency domain term. Although it is common for the terms to be used loosely with the result that they are often used interchangeably. In theory and with perfect measuring equipment, phase noise measured to an infinite carrier offset would provide the same value as jitter. However, using practical test ...

The noise modifies the signal's mid-point crossing location, which creates jitter. Increasing the edge rate (i.e. reducing the transition time) minimizes this conversion of baseband amplitude noise to jitter. Baseband amplitude noise does not affect phase error (or phase noise).
