Minimally invasive procedures encompass surgical techniques that limit the size of incisions needed and so lessen wound healing time, associated pain and risk of infection. Surgery by definition is invasive and many operations requiring incisions of some size are referred to as open surgery, in which incisions made can sometimes leave large wounds that are painful and take a long time to heal. Minimally invasive procedures have been enabled by the advance of various medical technologies. An endo

Minimally invasive (MI) treatment offers an attractive alternative to managing carious lesions in a more conservative and effective manner, resulting in enhanced preservation of tooth structure. The aim of this review was to summarize the evidence behind several MI alternatives for carious lesion management, including the use of sealants, infiltration, atraumatic restorative treatment (ART), and selective carious tissue removal (e.g., indirect pulp capping, stepwise removal, or selective ...

Ablation allows the doctor to destroy the tumor (s) in a minimally-invasive way — using few or very small incisions. Ultrasound, CT or MRI images allow the doctor to see the liver in real time while performing the ablation procedure. Guided by images of the liver, the doctor places the ablation antenna into the center of the tumor.

Minimally invasive spinal surgery is done through small incisions in the back. Surgeons use special instruments, such as intraoperative radiographs, microscopes, and tubular retractors. Both types of surgery are intended to relieve back or leg pain. However, minimally invasive spinal surgery attempts to cut as little muscle as possible.
