Fossils of the Burgess Shale - Wikipedia

The significance of the Burgess Shale fossils, of course, is that they are images of soft body parts, usually lost as fossilization proceeds. At the time of the original find in 1909, such artifacts, especially ones of such ancient deposition were pricelessly rare.

Burgess Shale, fossil formation containing remarkably detailed traces of soft-bodied biota of the Middle Cambrian Epoch (520 to 512 million years ago). Collected from a fossil bed in the Burgess Pass of the Canadian Rockies, the Burgess Shale is one of the best preserved and most important fossil formations in the world.

The Burgess Shale is a fossil rich rock formation in the Canadian Rockies. The term was conceived by palaeontologist Charles Walcott to describe soft-bodied fossils preserved in sedimentary rock layers. The original discovery was made on a ridge between Wapta Mountain and Mount Field in 1909.

The Burgess Shale fossils are about 505 million years old, some 20 million years younger than those from Chengjiang. In fact, the Burgess Shale and Chengjiang have considerable overlap in faunal forms.

Burgess Shale - Fossil

The Burgess Shale fossils are some of the best preserved animal fossils on the planet. The animal fossil record mostly consists of the hard parts of organisms (biomineralized structures or mineralized tissues), such as teeth, bones, exoskeltons, and shells; while soft (labile) tissues are rarely preserved long enough to become a fossil. This is because these hard tissues are more resistant to decay and erosion; are more chemically and physically stable; and are less likely to be consumed . . .

Specific fossils are discussed in Fossils_of_the_Burgess_Shale#Notable_Burgess_Shale_fossils, including Anomalocaris (an amusing detective story), Opabinia (classified in the 1970s as part of a novel phylum, more recently as a fairly close relative of arthropods) and an outline of the messy halwaxiid debate including Wiwaxia, Orthrozanclus and Odontogriphus.

The Burgess Shale is a fossil-bearing deposit exposed in the Canadian Rockies of British Columbia, Canada. It is famous for the exceptional preservation of the soft parts of its fossils. At 508 million years old, it is one of the earliest fossil beds containing soft-part imprints. The rock unit is a black shale and crops out at a number of localities near the town of Field in Yoho National Park and the Kicking Horse Pass. Another outcrop is in Kootenay National Park 42 km to the south.

Pikaia gracilens is an extinct, primitive chordate animal known from the Middle Cambrian Burgess Shale of British Columbia. Sixteen specimens are known from the Greater Phyllopod bed, where they comprised 0.03% of the community. It resembled the lancelet and perhaps swam much like an eel. Its exact phylogenetic position is unclear.

Macroscopic algae are common fossils in the Burgess Shale site. The most commonly found species among them is Morania confluens. This species is found in crowded fragments in the rock slabs. Oddly enough, there are no other species of alga found fossilized in the same vicinity.

Certain fossil-bearing deposits have revealed amazingly fine-detailed anatomy of prehistoric soft-bodied invertebrate life-forms such as those found in the Burgess Shale of Canada or Hunsruck Shales of Germany. More commonly found invertebrate fossils are those of hard-bodied creatures such as crustaceans.
